

305. Interaction at a Distance in Conjugated Systems. Part II.¹
The Preparation and Basicities of a Series of 4-Styryl- and 4-Phenylethynyl-pyridines.

By A. R. KATRITZKY, D. J. SHORT, and A. J. BOULTON.

The preparation of a series of 4-styryl- and 4-phenylethynyl-pyridines and their 1-oxides is described. The basicities of the pyridines indicate that interaction between the substituents on the benzene rings and the pyridine ring is quite small, but is larger in the styryl than in the phenylethynyl compounds.

A SERIES of styryl- and phenylethynyl-pyridines and -pyridine 1-oxides has been prepared and the pK_a values have been measured to investigate interaction over distances greater than those for the substituted phenyl-pyridines and 1-oxides studied in the preceding paper.¹

Preparation of Compounds.—Aromatic aldehydes (I) with γ -picoline (II) gave substituted γ -stilbazoles (III) which were converted by bromination and dehydrobromination into the corresponding acetylenes (IV); the acetylenes yielded the *N*-oxides (V) by oxidation with perbenzoic acid. The stilbazole *N*-oxides (VI) were obtained more efficiently by reaction of the aldehyde (I) with γ -picoline 1-oxide than by direct oxidation of the stilbazoles (cf. ref. 2). Details are recorded in Table 1. The pK_a values in Table 2 were measured by the spectrophotometric method.

Discussion.—The basicities of 3- and 4-substituted pyridines can be correlated by Hammett's equation,³ and by using the determined ρ value of 5.7, Hammett σ constants have now been calculated for the substituted styryl and phenylethynyl groups (Table 2).

1518 *Interaction at a Distance in Conjugated Systems. Part II.*

Previous "normal" σ_p values for the Ph·CH:CH· and Ph·C:C· groups are respectively -0.05 and $+0.19$ as derived from ionisation constants of benzoic acids and hydrolysis rates of ethyl benzoates.⁴ However, the solvolysis of benzyl toluenesulphonates, a reaction which depends strongly on electron-donor properties of substituents, would need constants much more negative (*ca.* -1.0 and 0.0) to be correlated.^{4,5} We therefore consider our values to be in reasonable agreement with the "normal" σ_p constants. The σ_p values in Table 2 show that the styryl group acts as an electron donor and the phenylethynyl group as an electron acceptor, in agreement with previous work.⁶ The σ_p values within each series of substituted compounds show that the effect of a substituent in the phenyl ring is transmitted more strongly through an ethylenic than through an acetylenic group. This is in line with the known ability of ethylenic groups to interact more strongly with an adjacent unsaturated system than do ethynyl groups.⁶ Comparison of these results with those for phenylpyridines¹ indicates that interaction in the series between the substituent and pyridine ring is in the order (Hammett ρ values are given in parentheses): X·C₆H₄·Py (0.97 ± 0.03) \sim X·C₆H₄·CH:CH·Py (0.85 ± 0.07) $>$ X·C₆H₄·C:C·Py (0.44 ± 0.04), but the effects are small in all cases compared with the effect of substituents directly in the pyridine ring ($\rho = 5.71 \pm 0.30$).³

EXPERIMENTAL

4-Styrylpyridines.—The aromatic aldehyde (0.08 mole), 4-picoline (8 g.), and acetic anhydride (20 g.) were refluxed under nitrogen for 30 hr. The mixture was dissolved in chloroform or ether and extracted with aqueous hydrochloric acid (8N; 2×50 c.c.); basification of the extracts with ammonia precipitated the product.

4-Phenylethynylpyridines.—These compounds were made by a known method.⁷ 4-Phenylethynylpyridine formed a *picrate*, needles, m. p. $182-183^\circ$ (decomp.), from ethanol (Found: C, 55.6; H, 3.1. C₁₉H₁₂N₄O₇ requires C, 55.9; H, 3.0%); a *picrolonate*, needles which decomposed at *ca.* 220° , from ethanol (Found: C, 62.0; H, 4.0. C₂₃H₁₇N₅O₅ requires C, 62.3; H, 3.9%); and a *boron trichloride complex* (cf. ref. 9), needles, m. p. $154-158^\circ$, from ethanol (Found: C, 52.5; H, 3.4. C₁₃H₉NBCl₃ requires C, 52.6; H, 3.0%).

2-Phenylethynylpyridine, prepared (yield 68%) by the literature method,⁸ had b. p. $106-108^\circ/0.2$ mm. (lit.,⁸ b. p. $160-164^\circ/3-4$ mm.); it solidified and then formed prisms, m. p. $29-32^\circ$, from ether-light petroleum. The *picrate* formed needles, m. p. $152-153^\circ$ (decomp.), from ethanol (Found: C, 56.4; H, 3.0%), and the *picrolonate* formed yellow needles, m. p. $165.5-166.5^\circ$, from ethanol (Found: C, 61.9; H, 4.1%).

4-Phenylethynylpyridine 1-Oxides.—The phenylethynylpyridine (0.01 mole) and perbenzoic acid in chloroform¹⁰ (70 c.c. of 0.29M-solution) were kept at 20° for 2 days. The whole was digested at 50° with potassium carbonate (6 g.) and water (1 c.c.), and filtered, and the filtrate dried (MgSO₄). The oxide was recovered by evaporation.

4-Phenylethynylpyridine 1-oxide picrate crystallised in needles, m. p. $147.5-148.5^\circ$, from ethanol (Found: C, 53.9; H, 3.0. C₁₉H₁₂N₄O₈ requires C, 53.8; H, 2.9%).

4-Styrylpyridine 1-Oxides.—The methyl-, methoxy-, dimethylamino-, and chloro-compounds were prepared from the aldehyde, 4-picoline 1-oxide, and methanolic potassium methoxide by the method of ref. 2. The nitro-analogue was prepared by oxidation² of the nitrostyrylpyridine by peracetic acid.

We thank Dr. A. S. Bailey for his interest.
