

72. *Vibrational Spectra and Chemical Thermodynamic Properties of the Difluorobenzenes.*

By J. H. S. GREEN, W. KYNASTON, and H. M. PAISLEY.

The infrared absorption spectra (liquid, solutions, and vapour phase) and the Raman spectrum (liquid) of *o*-difluorobenzene have been measured and a complete vibrational assignment made. This has been used, together with a revised assignment for *m*-difluorobenzene and a completed assignment for *p*-difluorobenzene, to calculate the chemical thermodynamic properties for all three isomers in the ideal-gas state at 273·16°, 298·16°, and 300—1500°K.

THE infrared spectrum (2—15 μ) of *o*-difluorobenzene has been reported¹ but there is no complete record of the Raman displacements apart from a quotation² of some frequencies. In the present work the infrared measurements have been extended to 45 μ and the Raman spectrum recorded. The observed frequencies have been fully interpreted and complete assignments made to the normal frequencies. Some revisions of the assignment³ for *m*-difluorobenzene are now suggested to bring the fundamentals into line more closely with those given recently⁴ for other *m*-disubstituted benzenes. The previous assignment for *p*-difluorobenzene⁵ has now been completed by an attribution of the lowest b_{3u} fundamental.

EXPERIMENTAL

The original commercial sample of *o*-difluorobenzene was shown by gas chromatography and nuclear magnetic resonance spectroscopy to contain *ca.* 5% of impurity, identified by infrared spectroscopy as *o*-chlorofluorobenzene.⁶ Distillation afforded material containing *ca.* 1% of this impurity. The infrared spectra were recorded for the liquid compound and for solutions in carbon tetrachloride and carbon disulphide by using the double-beam prism-grating instrument (4000—560 cm^{-1}) as before;⁷ for the liquid and the gaseous state (10 cm. cell at 100°) a Grubb-Parsons GS3 spectrometer (600—400 cm^{-1}) was used, and for the liquid compound a Grubb-Parsons DM3 (25—50 μ) monochromator with a single-beam source unit. Raman spectra were measured photoelectrically and photographically (Kodak 0a—0 plates) with a Hilger source unit and E612 spectrograph.

The spectra are assembled in Table I. Only one frequency is coincident with frequencies

belonging to *o*-chlorofluorobenzene;⁶ this band, at 441 cm.⁻¹, was shown not to change in relative intensity on purification and its relative intensity in both infrared and Raman spectra was too great to be due entirely to impurity.

ASSIGNMENT

o-Difluorobenzene.—The molecule has C_{2v} symmetry and, with the z -axis as the two-fold axis and the x -axis as that perpendicular to the ring,⁸ the thirty fundamentals comprise $(11a_1 + 10b_2)$ planar plus $(5a_2 + 4b_1)$ non-planar modes. With the dimensions C-F = 1.35 Å,⁹ C-H = 1.084, C-C = 1.397 Å, and all angles 120°, the moments of inertia are found to be $I_{xx} = 381.49$, $I_{yy} = 642.97$, $I_{zz} = 261.52 \times 10^{-40}$ g. cm.², so that

fund. = fundamental. w = weak; m = medium; s = strong; v = very; sh = shoulder. Region 2000–3000 cm.⁻¹ omitted; additional weak Raman lines were observed at 2825, 2915, and 2977 cm.⁻¹.

the least moment coincides with the twofold axis. Hence a_1 fundamentals should yield bands with A -type contours, b_2 fundamentals give B -type contours, and b_1 fundamentals C -type contours. Approximate band envelopes were calculated by using the results of

Badger and Zumwalt¹¹ and the *PR* separations found to be 12, 8, and 11 cm.⁻¹ for the *A*, *B*, and *C* types respectively.

The CH stretching fundamentals are not all adequately resolved and are assigned schematically as summarised in Table 2. However, the expected pair of frequencies derived from the benzene vibration at 1600 cm.⁻¹ are resolved and the lower is placed in the *a*₁ class and the higher in the *b*₂ class as for other *o*-disubstituted benzenes and in accord with the calculations for *o*-xylene.¹² Also in the *a*₁ class must be placed the bands with *A*-type contours centred at 1514, 1277, 1155, and 1025 cm.⁻¹. The contours around 750 cm.⁻¹ are somewhat confused since the *P* branch of the *A*-type contour centred at 762 cm.⁻¹ is overlapped by the *R* branch of the adjacent, extremely strong, *b*₁ fundamental at 749 cm.⁻¹. The Raman intensities support the assignments to *a*₁ and *b*₁ modes. Similarly, the pair of frequencies at 546 and 566 cm.⁻¹ are overlapped but the lower appears to have a *B*-type and the higher an *A*-type contour, and the Raman intensities again support this. The lowest *a*₁ fundamental is expected at about 200 cm.⁻¹ and is assigned to the strong Raman displacement of 196 cm.⁻¹ (cf. *o*-xylene, 180 cm.⁻¹; *o*-fluorotoluene, 186 cm.⁻¹; *o*-cresol, 190 cm.⁻¹). A final *a*₁ mode is derived from *v*₁₄ of benzene and therefore expected at around 1300 cm.⁻¹, though it is often only a weak band and somewhat elusive. The shoulder at 1313 cm.⁻¹ is a reasonable attribution though the fundamental may be coincident with the *b*₂ mode suggested at 1292 cm.⁻¹. There are also three other *B*₂ levels in this region, namely 1206 + 196 = 1302, 566 + 749 = 1315, and 450 + 856 = 1306.

Four *b*₂ fundamentals can be assigned clearly on a basis of the observed *B*-type contours of bands centred at 1464, 1214, 1103, and 857 cm.⁻¹ and a fifth is evidently at 546 cm.⁻¹. The *b*₂ fundamental derived from *v*₄ is that proposed at 1292 cm.⁻¹, and the lowest is expected at *ca.* 400 cm.⁻¹ and is assigned to the 439 cm.⁻¹ medium-intensity Raman line which appears as a definite shoulder in the infrared spectrum.

The five *a*₂ modes are forbidden in the infrared spectrum of the vapour and are usually only weak in the Raman effect. The two highest are essentially out-of-plane hydrogen-bonding modes, *γ*(CH), and are expected at *ca.* 980 and 860 cm.⁻¹; the former can therefore be readily assigned to the weak infrared band in the liquid at 982 cm.⁻¹. A band of medium intensity is observed in the liquid-state spectrum at 840 cm.⁻¹ but it is too strong to be entirely due to an *a*₂ fundamental and, further, it appears as a shoulder on the 856 cm.⁻¹ band in the vapour spectrum. This presumably arises from 551 + 289 = 840 (*B*₁). The *a*₂ fundamental is assumed to be at about this position and some support for this is found in the usual analysis of the bands in the 1600–1900 cm.⁻¹ region in terms of combination and overtones of the *γ*(CH) modes. Two further *a*₂ fundamentals are assigned as weak bands at 705 and 596 cm.⁻¹, whilst the lowest involving essentially out-of-plane bending of the C–F bonds is the strong Raman displacement of 196 cm.⁻¹; as in *o*-xylene,^{4,12} the lowest *a*₁ and *a*₂ frequencies are accidentally coincident.

Three of the *b*₁ fundamentals, at 929, 749, and 450 cm.⁻¹, are readily identified by the *C*-type contours and the fourth is assigned to the strong infrared band and Raman line at 298 cm.⁻¹. These assignments of the out-of-plane classes are in reasonable accord with the results of calculations.^{2,13}

m-Difluorobenzene.—The revisions of the assignment³ for *m*-difluorobenzene are made as follows. In the *a*₁ class it is clear that two fundamentals cannot be placed at 1257 and 1279 cm.⁻¹. One of these frequencies is acceptable as the fundamental and is the latter, with its *Q* branch at 1286 cm.⁻¹; the former is 736 + 524 = 1260 (*A*₁) which has probably borrowed intensity from the fundamental. The required new fundamental is certainly at 1608 cm.⁻¹ where it is evidently unresolved from its *b*₂ counterpart. The *Q* branches of other *a*₁ fundamentals are taken as 1456, 1066, and 735 cm.⁻¹; the ring breathing mode

¹¹ Badger and Zumwalt, *J. Chem. Phys.*, 1938, **6**, 711.

¹² Kovner and Bogomoloff, *Optika i Spektroskopiya*, 1959, **7**, 751.

¹³ Whiffen, "Molecular Spectroscopy," Conference held by the Institute of Petroleum, London, 1954, p. 126.

which appears as a very strong Raman line at 1008 cm^{-1} is absent from the infrared spectrum.

In the b_2 class (b_1 of ref. 3) the Q branch of the lower $\nu(\text{CC})$ mode is taken at 1493 cm^{-1} . The next two fundamentals are derived from ν_3 and ν_4 of benzene and are lost in the infrared spectrum beneath the strong bands at 1257 and 1279 cm^{-1} . They are taken to be at 1290 and 1265 cm^{-1} on a basis of their values in other m -disubstituted benzenes where the X -sensitive a_1 fundamental has moved to lower frequencies and left the other fundamentals exposed (e.g. m -dichlorobenzene, 1295 and 1255 cm^{-1} ; m -dibromobenzene, 1292 and 1256 cm^{-1}). Bands at 458 and 478 cm^{-1} were previously both candidates for the lowest b_2 mode and the former was preferred; however, it is now ² known that it has a C -type contour and must be assigned to the infrared-active out-of-plane class, b_1 ; the b_2 mode is now placed at 478 cm^{-1} .

The one other change in the b_1 class is the choice of 978 cm^{-1} rather than 862 cm^{-1} for the highest, $\gamma(\text{CH})$ mode. The a_2 class remains as before.

p-Difluorobenzene.—The revised assignment ⁵ for this molecule has received confirmation from intensity measurements ¹⁴ and from further band contour studies. ¹⁵ A band at 163 cm^{-1} in the vapour and 164 cm^{-1} in the liquid has been observed by one of us ¹⁶ and may be assigned to the missing b_{3u} fundamental; the calculated value ¹⁴ was 168 cm^{-1} . A very weak Raman shift of 165 cm^{-1} had been reported ⁵ but not interpreted

as a fundamental. The complete assignment, together with a revised description of the modes,¹⁷ is given in Table 2.

A sum rule for the square of the out-of-plane frequencies was used by Nielsen *et al.* to justify their assignments³ for *m*-difluorobenzene. With the present values, $\sum \nu^2$ is 4.26, 4.19, and 4.15×10^6 for the *o*-, *m*-, and *p*-isomers, respectively; this agreement seems satisfactory.

^a Standard heat, standard free energy, and common logarithm of the equilibrium constant for the formation of the difluorobenzene by the reaction: $6C$ (graphite) + $2H_2(g)$ + $F_2(g)$ = $C_6H_4F_2(g)$.

THERMODYNAMIC PROPERTIES

The values for the fundamental vibrational frequencies given in Table 2 were used with the aid of tables¹⁸ to calculate the vibrational contribution to the thermodynamic functions: the free-energy function $(G^\circ - H_0^\circ)/T$, heat-content function $(H^\circ - H_0^\circ)/T$, entropy S° , and heat capacity C_p° . For the rotational contributions, the product of the principal moments of inertia of the *o*-isomer using the above values is $6.414 \times 10^{-113} \text{ g.}^3 \text{ cm.}^6$. For the *m*- and the *p*-isomer, the C-F distance was taken⁹ as 1.30 Å, other distances and angles as in the *o*-compound, and the products of the principal moments of inertia were found to be 7.255 and $6.364 \times 10^{-113} \text{ g.}^3 \text{ cm.}^6$, respectively. The symmetry number is 2 for the *o*- and the *m*- and 4 for the *p*-isomer. The resulting total values for the thermodynamic functions for 273.16, 298.16, and 300–1500°K are given in Table 3; all relate to one mole of the difluorobenzene in the ideal-gas state at one atmosphere pressure.

Values for the heats of formation of the gaseous difluorobenzenes at 298.16°K have been reported¹⁹ and were used with the present results, and values of the thermodynamic functions for C (graphite),²⁰ H₂(g)²⁰, and F₂(g)²¹ to find ΔH_f° at 0°K; the values were *o*-, -64.42; *m*-, -68.04; *p*-, -67.41 kcal./mole. From these, the heat ΔH_f° , free energy ΔG_f° , and logarithm of the equilibrium constant $\log_{10} K_f^\circ$, of formation, of the difluorobenzenes were calculated for the whole temperature range. At each temperature the mole fraction, N , of each isomer present at equilibrium was calculated; the values are given in Table 4.

TABLE 4.

Equilibrium mole fractions of the difluorobenzenes.

<i>T</i> (°K)	273.16	298.16	300	400	500	600	700	800	900	1000	1100	1200	1300	1400	1500

The entropies are sufficiently close to equality that the relative free energies are determined by the enthalpy term. As with the xylenes,²² the order of thermodynamic stability throughout the temperature range is *m*- > *p*- > *o*-; in the cresols, however, the order has been found²³ to be *m* > *o*- > *p*.

We thank Mr. R. R. Collerson and Mr. D. Harrop for the gas chromatographic examination, and Dr. I. J. Lawrenson for the nuclear magnetic resonance measurements.
